# 1 Introduction

The toxicity of metals to aquatic life is highly variable and depends on physical and chemical factors within a water body. Hardness has long been acknowledged as one such factor and is reflected in DEQ's current hardness dependent criteria, whereby the acute and chronic criteria are determined based on the total hardness of the receiving water body.

Hardness dependent copper criteria do not take into account the effects of other physicochemical properties that affect toxicity, leading to hardness dependent copper criteria being either over- or under-protective of aquatic life. The Biotic ligand model (BLM) based criteria outlined in the EPA's revised national recommended freshwater aquatic life criterion for copper takes into consideration copper toxicity influenced by a wide variety of water characteristics. Therefore, DEQ has updated the copper criteria for aquatic life to the US Environmental Protection Agency (EPA) 2007 recommended 304(a) criteria (EPA 2007a).

This action was identified in both the National Marine Fisheries Service (NMFS) and US Fish and Wildlife Service's (FWS) biological opinions on EPA's action on Idaho's criteria for toxic substances to support aquatic life (NMFS 2014; FWS 2015). These biological opinions concluded that the hardness dependent copper criteria (as well as other toxics criteria) were under-protective of aquatic life support and would jeopardize the continued existence of species listed under the Endangered Species Act (ESA) and adversely modify their designated critical habitat. Their recommendation was to use EPA's 2007 copper criteria which uses the biotic ligand model (BLM) to predict water-body specific criteria by taking into account other physicochemical properties of the water (e.g., pH, dissolved organic carbon, etc.).

This guidance will provide background on copper toxicity and the BLM, and will detail how DEQ will implement the copper criteria for aquatic life. It will discuss data requirements, spatial and temporal representation, and options for reconciling multiple time variable criteria from a single location. It will discuss procedures for estimating criteria when data are limited, and outline how to derive criteria for permitting and assessment purposes.

## 1.1 Purpose

The purpose of this document is to provide guidelines to DEQ staff, the regulated community, and the general public (hereafter referred to as users) for calculating the copper criteria for aquatic life using the BLM.

This guidance will address the following issues associated with implementation of the BLM:

- How to use site-specific water chemistry data to derive BLM copper criteria
- Accounting for spatial and temporal variability when using the BLM
- Methods for estimating or deriving protective copper criteria when BLM input data are not available

- ~~How to produce predictable and repeatable water quality criteria from multiple instantaneous water quality criteria (IWQC) for deriving water quality based effluent limits (WQBELs)~~
- How to reconcile multiple IWQCs in order to derive water quality criteria for developing water quality based effluent limits or identifying impairments for the integrated report

This guidance has been developed in coordination with the Idaho Pollutant Discharge Elimination System Program and is limited to developing copper criteria; it ~~and~~ does not detail procedures for development of NPDES permits or general policies and procedures for Clean Water Act assessments. For more information on development of permit limits please see DEQ's most recent version of *Effluent Limit Development Guidance* (ELDG; DEQ 2017a). For more information on listing and assessment methodologies please see DEQ's most recent version of *Water Body Assessment Guidance* (WBAG; DEQ 2016).

## 1.2 Sources of Copper in the Environment

Copper is a natural element that occurs in the earth's crust at low levels. Natural processes, such as air deposition and erosion of parent material containing copper contribute to the presence of copper in surface waters. In addition, human activities (e.g., mining operations, agriculture, etc.) may lead to increased erosion or sediment transport, which could result in higher copper concentrations than would occur from natural weathering alone (ATSDR 2004).

Other anthropogenic activities can lead to elevated levels of copper in the aquatic environment. Anthropogenic sources of copper in surface waters include domestic waste water, urban storm water runoff, active milling and mining, abandoned mine runoff, electroplating operations, corrosion of copper in plumbing and construction materials, effluents from power plants that use copper alloys in the heat exchangers of their cooling systems, leachate from municipal landfills and direct addition of copper sulfate to surface waters as a algaecide (ATSDR 2004).

## 1.3 Effects of Copper on Aquatic Life

Copper is an essential micronutrient for plants, animals, and humans. However, at concentrations above the recommended levels, copper can become acutely toxic, especially to aquatic organisms (Scannell 2009, Eisler 1998).

Chronic effects of copper include inhibition of photosynthesis, metabolism, and growth in aquatic plants and algae; reduced feeding, growth, and reproduction, as well as gill damage in aquatic invertebrates; and significant effects on behavior, growth, migration, changes in metabolism and organ or cellular damage, and changes in olfactory responses in freshwater fish species (Eisler 1998, Sommer et al. 2016).

### 1.3.1 Effects of Physical and Chemical Properties on the Toxicity of Copper

Copper toxicity in aquatic environments depends on the ability of copper to bind to a biological receptor or a cell surface of an organism (e.g., the gill surface of a fish). This receptor is known

as a biotic ligand and is the location where interactions with metals occur. Copper that is free to bind to the receptor is considered bioavailable copper.

Bioavailability of copper in freshwater is related to the following:

- Chemical species of copper (the chemical forms of copper, such as  $\text{Cu}^{2+}$ )
- Complexation of copper with organic ligands<sup>1</sup>
- Complexation of copper with inorganic ligands

Several physicochemical properties can affect copper speciation and the availability of ligands for complexation with copper. The most important of these factors are the concentration of dissolved organic carbon (DOC), which complexes with copper, and pH, which controls copper speciation.

In addition, other cations compete with copper for binding at the biotic ligand. The most common major cations present in surface waters are calcium ( $\text{Ca}^{2+}$ ), magnesium ( $\text{Mg}^{2+}$ ), sodium ( $\text{Na}^+$ ), and hydrogen ( $\text{H}^+$ ). Therefore, to reliably estimate concentrations of available to exert toxicity at any given sampling location, it is necessary to account for these factors.

Figure 1 presents a conceptual framework for how these processes affect the ability for a free copper to bind to a biotic ligand such as the gill surface.

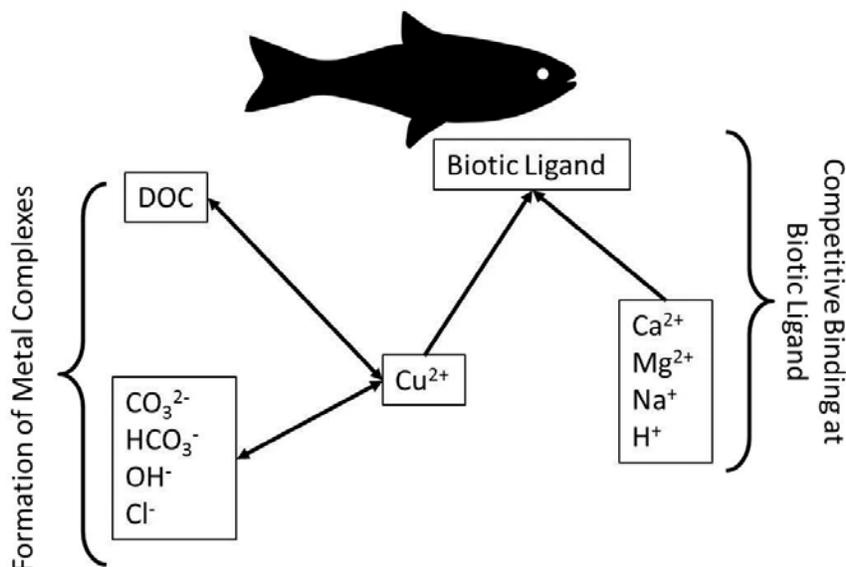

Figure 1. Conceptual model of how chemical speciation, metal complexation, and competition of other cations with copper for binding at biotic ligands affect metal bioavailability. Free metal ion ( $\text{Me}^{2+}$ ) complexes with dissolved organic carbon (DOC) and inorganic ligands. In addition, cations such as  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  compete with the remaining free metal to bind to the biotic ligand, limiting the effects of the metal on the organism. (Figure adapted from Windward Environmental, LLC (<http://www.windwardenv.com/biotic-ligand-model/>)).

<sup>1</sup> A "ligand" is a complexing chemical (ion, molecule, or molecular group) that interacts with a metal like copper to form a larger complex (EPA 2007).

In general, in waters with low DOC, low pH, and low hardness, the fraction of copper that is bioavailable is greatest. As DOC, pH, and hardness increase, the bioavailability and thus toxicity of copper decreases.

## 1.4 Impaired waters and TMDLs

DEQ relies heavily on biological monitoring to determine impairments; direct measures of the aquatic community are used to determine support of aquatic life uses (see Jessup 2011, DEQ 2016). Waters that have aquatic communities that have been modified by human activities beyond the natural range of reference conditions are considered impaired and are subjected to additional monitoring and analysis to determine the cause or causes of impairment. Impairment listings are then refined to reflect the actual cause of the impairment. Waters may also be sampled for pollutants like copper, for example when associated with Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) or when that type of assessment is needed for regulatory activities.

Currently, there are very few waters in Idaho where copper has been identified as impairing aquatic life. The 2012 Integrated Report (IR)—the most recent approved IR—identified 43 miles of stream and river where copper was impairing aquatic life (DEQ 2014). This represents less than 0.05% of the 95,119 stream and river miles that DEQ reported on in the 2012 IR.

Of the 43 miles of impaired stream and rivers, 22 are covered under the approved- *Lower Clark Fork River Subbasin Assessment and Total Maximum Daily Load* (DEQ 2007). According to the subbasin assessment and TMDL, the source of the copper impairment is from mine wastes in the Clark Fork River watershed in Montana including sources within the Milltown Reservoir/Clark Fork River Superfund Site. Thus, Montana DEQ is responsible for reductions of copper to meet the criteria at the Idaho border (DEQ 2014).

In addition, 15 miles of impaired streams and rivers are in areas that are impacted by the Blackbird Mine and are under active remediation under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) (DEQ 2014).

A 6-mile reach of Prichard Creek, a tributary to the North Fork Coeur d'Alene River, is also impaired due to copper. The Prichard Creek watershed is located within the Coeur d'Alene Mining District. Similar to the adjacent Bunker Hill Mining and Metallurgical Superfund Site, the Prichard Creek watershed contains multiple historic mine and mill sites. Cleanup of priority historic sources (e.g., mill sites) has occurred in the watershed under CERCLA. Additional water quality improvement work, including ecological restoration under a Natural Resources Damage Assessment and Restoration (NRDAR) program, is being planned. Figure 2 shows the scope and location of waters that have been identified as impaired for aquatic life by copper.

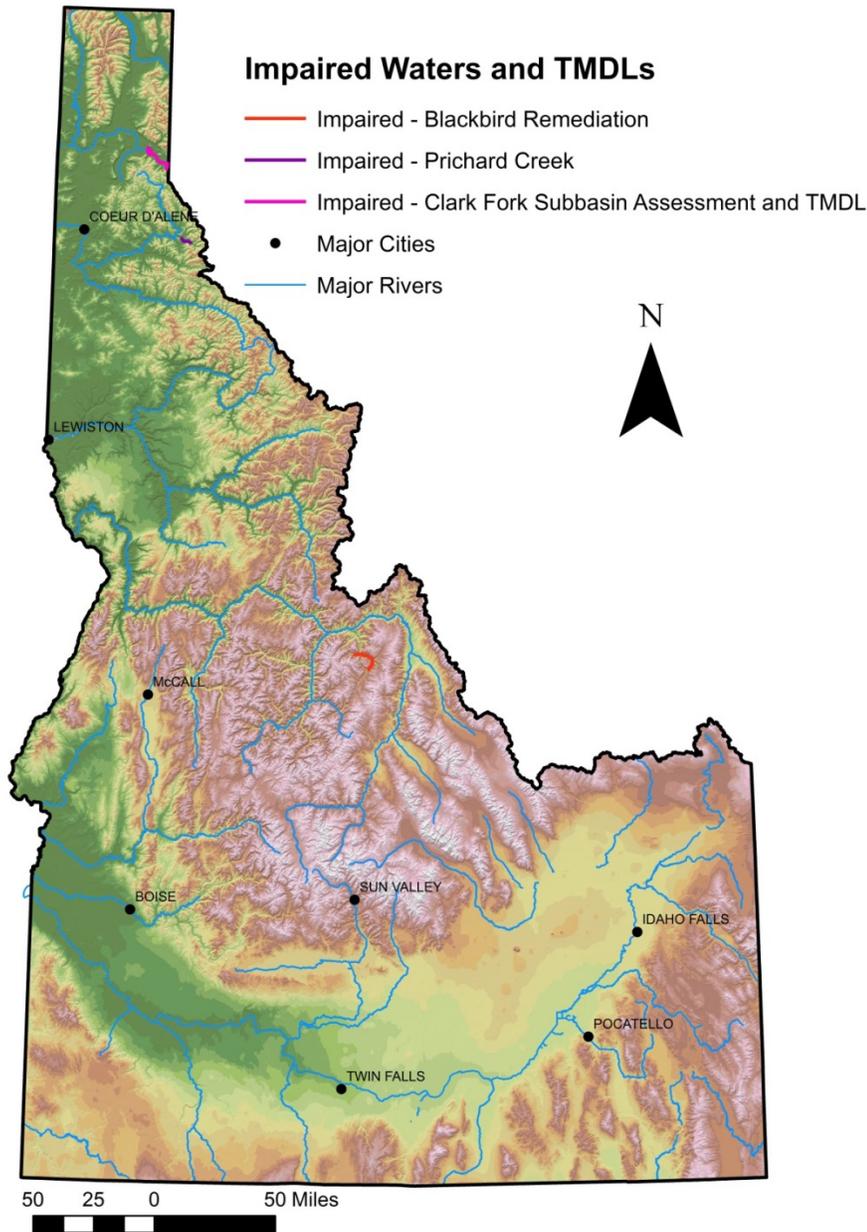

Figure 2. Map of Idaho showing the limited scope of waters where aquatic life is impaired by copper.

## 1.5 NPDES Permits in Idaho

There are presently relatively few point source dischargers in Idaho that have copper effluent limits. As of the date of this guidance, there are approximately 390 municipal, industrial, commercial, and aquaculture dischargers with NPDES permits in Idaho; 20 dischargers have

copper effluent limits. Of these permittees, 8 are mines, 10 are municipal waste water treatment plants, and 2 are fish hatcheries (Figure 3).

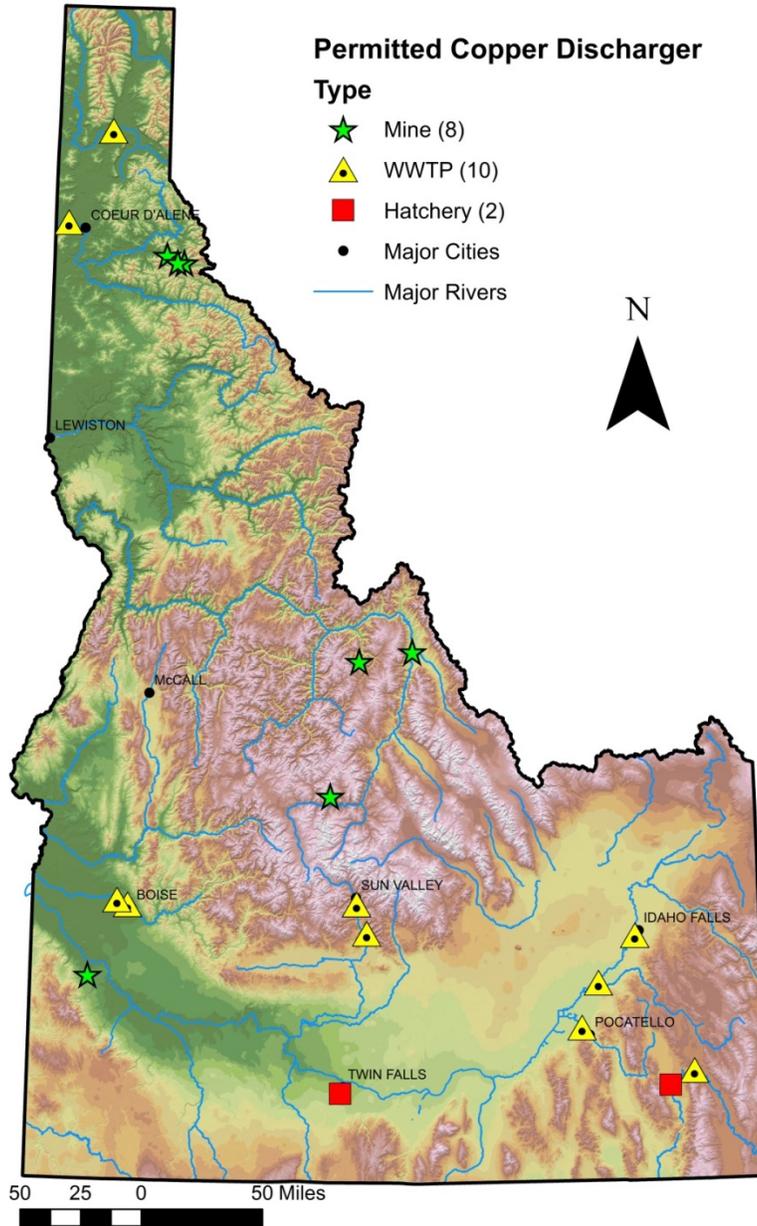

Figure 3. Map of Idaho showing the location and type of dischargers with copper effluent limits.

## 2 DRAFT Idaho Aquatic Life Criteria for Copper

Idaho’s numeric copper criteria for aquatic life are found in IDAPA 58.01.02.210. Derivation of the Idaho aquatic life criteria for copper requires the use of the Biotic Ligand Model, or BLM, version 3.1.2.37 (Windward 2015) to calculate acute and chronic copper criteria.

An excerpt of the relevant table and footnotes are presented in Figure 4.

A		B Aquatic life	
(Number) Compound	a	b	b
	CAS Number	CMC (µg/L) B1	CCC (µg/L) B2
6 Copper	7440508	12.3 r	7.6 r

Table Footnotes

**r. Aquatic life criteria for copper are shall be derived in accordance with Subsection 210.03 c.v. from the Biotic Ligand Model, Version 3.1.2.37 (October 2015), US EPA WQC Calculation for Copper available at [www.deq.idaho.gov](http://www.deq.idaho.gov). For comparative purposes only, the example values displayed in this table correspond to the model Biotic Ligand Model output based on the following inputs: temperature = 14.9°C, pH = 8.16, dissolved organic carbon = 1.4 mg/L, humic acid fraction = 10%, Calcium = 44.6 mg/L, Magnesium = 11.0 mg/L, Sodium = 11.7 mg/L, Potassium = 2.12 mg/L, Sulfate = 46.2 mg/L, Chlorine chloride = 12.7 mg/L, alkalinity = 123 mg/L CaCO<sub>3</sub>, and Sulfide = 1.00e<sup>-8</sup> mg/L. Sulfide should be input as a default of near zero (e.g., 1.00e<sup>-8</sup>).**

*Table Footnote r. Effective on the date EPA issues written notification that the revisions adopted under Rule Docket No. 58-0102-1502 have been approved. See Subsection 210.01.d.iii.*

*Footnote r is not effective for CWA purposes until the date EPA issues written notification that the revisions adopted under Rule Docket No. 58-0102-1502 have been approved.*

Figure 4. Excerpt from Idaho Water Quality Standards denoting relevant table and footnotes referencing the use of the biotic ligand model to derive copper criteria for aquatic life.

Additional rule language regarding applicability of the copper criteria for aquatic life are found in Section 210.03.c.v and are as follows:

v. Copper Criteria for Aquatic Life.

(1) Aquatic life criteria for copper shall be derived using:

(a) Biotic Ligand Model (BLM) software that calculates criteria consistent with the “Aquatic Life Ambient Freshwater Quality Criteria – Copper”: EPA-822-R-07-001 (February 2007), available at [www.deq.idaho.gov/58-0102-1502](http://www.deq.idaho.gov/58-0102-1502); or

(b) An estimate that is based on a scientifically sound method and protective of the designated aquatic life use.

(2) To calculate copper criteria using the BLM, the following parameters from each site shall be used: temperature, pH, dissolved organic carbon (DOC), calcium, magnesium, sodium, potassium, sulfate, chloride, and alkalinity. The BLM inputs for humic acid (HA) as a proportion of DOC and sulfide shall be

based on either measured values or the following default values: 10% HA as a proportion of DOC,  $1.00 \times 10^{-8}$  mg/L sulfide. Measured values shall supersede any estimate or default input.

(3) BLM input measurements shall be planned to capture the most bioavailable conditions for copper.

(4) A criterion derived using BLM software shall supersede any estimated criterion. Acceptable BLM software includes the “US EPA WQC Calculation” for copper in BLM Version 3.1.2.37 (October 2015), available at [www.deq.idaho.gov/58-0102-1502](http://www.deq.idaho.gov/58-0102-1502).

(5) Implementation Guidance for the Idaho Copper Criteria for Aquatic Life. The “Implementation Guidance for the Idaho Copper Criteria for Aquatic Life” describes in detail methods for implementing the aquatic life criteria for copper using the BLM. This guidance, or its updates, will provide assistance to the Department and the public for determining minimum data requirements for BLM inputs, and how to estimate criteria when data are incomplete or unavailable. The “Implementation Guidance for the Idaho Copper Criteria for Aquatic Life” is available at the Department of Environmental Quality, 1410 N. Hilton, Boise, Idaho 83706, and on the DEQ website at [www.deq.idaho.gov](http://www.deq.idaho.gov).

It is important for users to note that these example values found in the criteria table at IDAPA 58.01.02.210 are not intended to represent default criteria values, nor are they the criteria that apply to any particular location as the locally applicable criterion will depend on local values of input parameters to the BLM.

### **3 General Implementation for Aquatic Life Criteria**

The following general implementation requirements for aquatic life criteria, found in Idaho Water Quality Standards (IDAPA 58.01.02.210.03) shall be applicable when implementing the copper criteria for aquatic life:

- When a mixing zone is authorized, the BLM derived chronic copper criterion will apply at the boundary of the mixing zone (Section 210.03.a).
- Water quality based effluent limits (WQBEL) shall be based on criteria exceedances only occurring during low flow conditions that meet the following criteria: the lowest one-day flow with a ten year occurrence (1Q10) for acute copper criteria, or based on an allowable exceedance occurring no more than once every three years (1B3). For chronic criteria, these are the lowest seven-day average low flow with a ten year recurrence (7Q10) or based on an exceedance for four consecutive days occurring no more than once every three years (4B3) (Section 210.03.b).
- The copper criteria for aquatic life will be expressed as concentration of dissolved copper (Section 210.03.c.iii).
- Acute criteria are criteria not to be exceeded for a one-hour average more than once in three years. Chronic criteria are not to be exceeded for a four-day average more than once in three years (Section 210.03.d.i).

In addition, the following implementation tools shall be available when implementing the Idaho copper criteria for aquatic life:

- Flow Tiered NPDES Permit limitations may be provided for dischargers with copper limits in accordance with Section 400.05.
- Intake Credits for Water Quality-Based Effluent Limitations may be allowed in accordance with Section 400.06.

All other water quality standards and Idaho Pollutant Discharge Elimination System (IPDES) rules and regulations, IDAPA 58.01.25, shall apply when implementing the Idaho copper criteria for aquatic life.

## 4 The Biotic Ligand Model

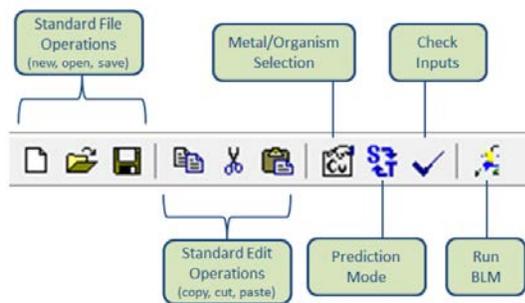

The Biotic Ligand Model (BLM) is a model that predicts toxicity of metals by estimating the bioavailability of the metal to bind to the biological receptor, or biotic ligand, such as the gill surface.

In contrast to hardness based criteria, which only account for competitive binding at biotic ligand sites by calcium and magnesium cations, the BLM also accounts for binding at biotic ligand sites by cations other than calcium and magnesium, as well as metal speciation and complexation with DOC and other inorganic ligands (Figure 1). EPA’s 2007 recommended aquatic life criteria for copper replaces the previously recommended hardness based equation with the BLM.

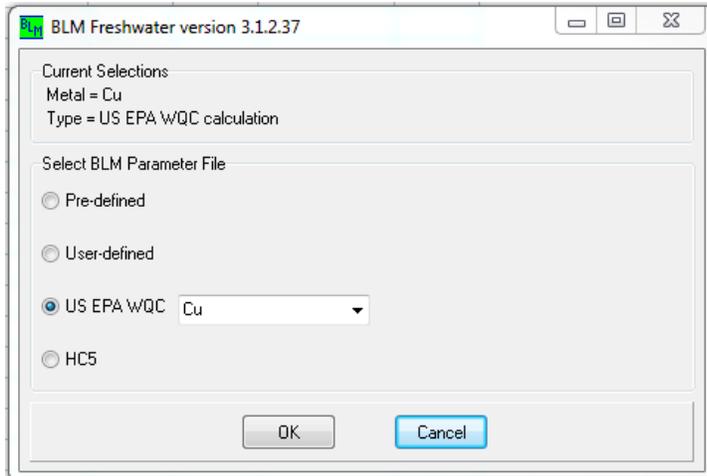

### 4.1 Overview of BLM Version 3.1.2.37

Version 3.1.2.37 is the most recent version of the BLM available at this time. The BLM Version 3.1.2.37 and associated Users Guide can be downloaded from <http://www.windwardenv.com/biotic-ligand-model/> or from DEQ’s website ([www.deq.idaho.gov](http://www.deq.idaho.gov)). More information can be found in the BLM User’s Guide (Windward 2015).

Users must be able to ensure they are using the BLM to return results consistent with EPA’s 2007 nationally recommended criteria. In version 3.1.2.37, users must select the “US EPA WQC” radio button and select “Cu” from the dropdown from the “Metal/Organism Selection” shortcut menu (Figure 5 and Figure 6).

**Figure 5. Shortcut toolbar key for BLM Version 3.1.2.37, indicating location of the Metal/Organism Selection shortcut. Taken from Figure 6-11 of the BLM User's Guide (Windward 2015).**

**Figure 6. Select US EPA WQC and Cu in order to return results consistent with EPA's 2007 Criteria.**

Users must also use the complete site chemistry; simplified site chemistry is not sufficient for calculating criteria under this guidance.

The BLM estimates copper concentrations that would result in acute and chronic effects to aquatic life in a water body based on the values of the following site-specific physical and chemical parameters:

- Temperature
- pH
- DOC
- Calcium
- Magnesium
- Sodium
- Potassium
- Sulfate
- Chloride
- Alkalinity
- Sulfide
- Humic acid

Each parameter will be discussed in more detail in Section 5.1.

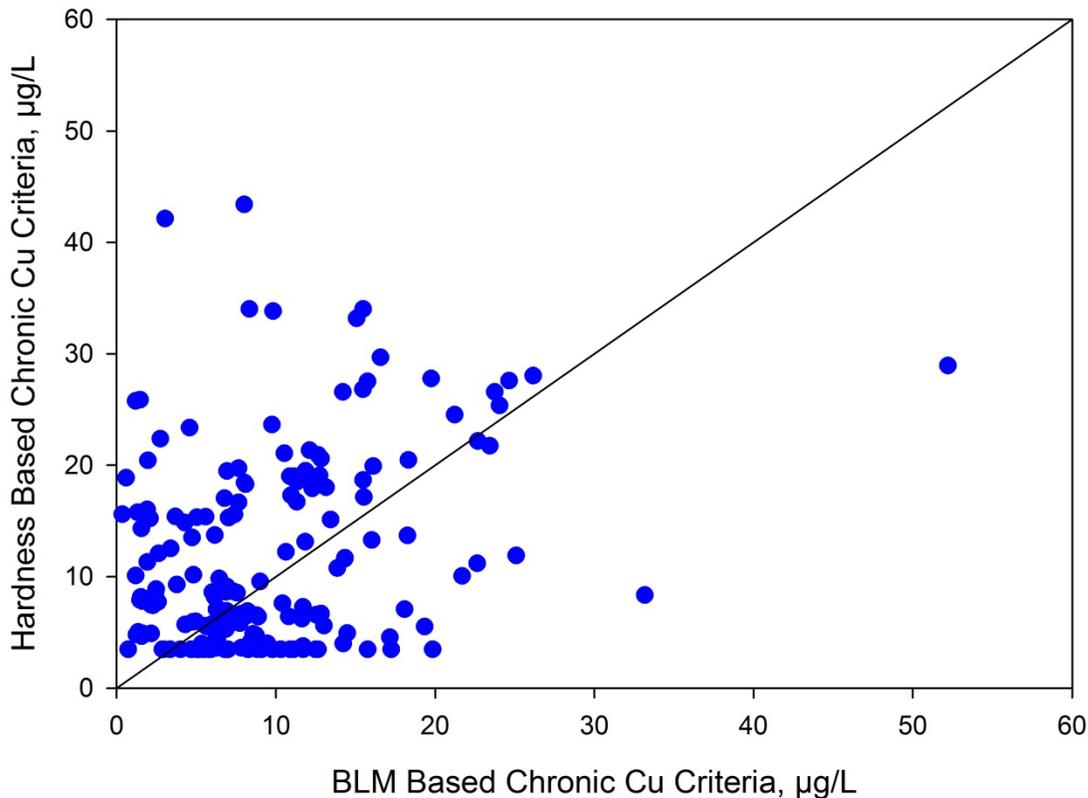

The model calculates both acute and chronic criteria based on these inputs. The criteria calculated from a single set of inputs are referred to as instantaneous water quality criteria

(IWQC). The IWQC represents the criteria that would be protective of aquatic life at the time that the data were collected. However, the input data are variable over time and space, so any single IWQC is time and place specific and will not necessarily be protective of aquatic life at any given site; if site chemistry changes, individual IWQCs will change. The same applies to the current hardness based criteria.

## **4.2 Comparison to Hardness Based Criteria**

Because the BLM incorporates copper speciation and complexation in addition to competitive binding at biotic ligand sites by cations, it better predicts the toxic effects of exposure to dissolved copper in the aquatic environment than the hardness based equation.

The BLM produces more accurate predictions of toxic effects from copper in a variety of natural waters than the hardness based criterion equation, which has been found to produce highly variable and often inaccurate predictions of actual toxicity (NMFS 2014).

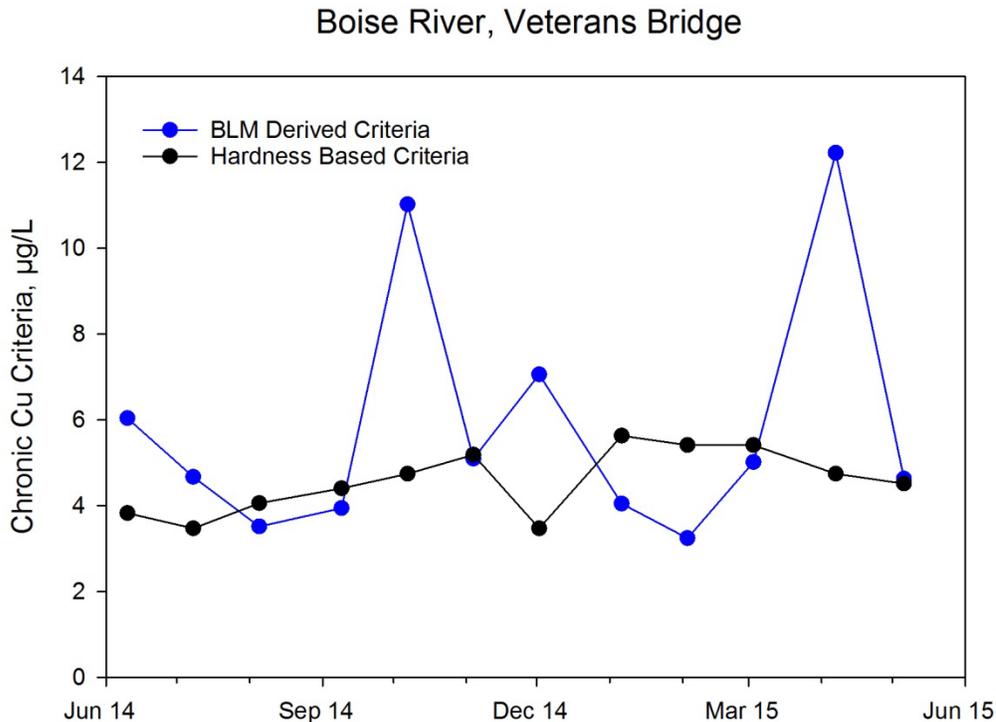

**Figure 7. Comparison of BLM derived to hardness based criteria calculated from sites monitored as part of the *Statewide Monitoring for Inputs to the Copper Biotic Ligand Model* (DEQ 2017b)(draft DEQ 2017) . The solid black line is the 1:1 line; sites above the line have BLM criteria that are more stringent than the hardness based criteria, sites below the line have BLM criteria that are less stringent. Idaho's hardness based criteria included a minimum hardness floor of 25 mg/L.**

While the BLM does provide more accurate and precise predictions of toxic effects from a given copper concentration, it is important to note that the BLM does not always provide more stringent criteria.

For example, when waters have relatively high DOC concentrations, such as in the case of downstream from a municipal wastewater treatment facility, BLM derived criteria will likely be less stringent than those derived from the hardness based criteria equation. Conversely, in areas with very limited organic inputs, or with more acidic conditions (lower pH), BLM derived criteria may be more stringent than criteria derived from the hardness based criteria equation.

Figure 7 shows comparisons of acute and chronic criteria derived from both the hardness based equation and the BLM for 188 stream sites monitored for the *Statewide Monitoring for Inputs to the Copper Biotic Ligand Model* (draft DEQ 2017b) showing the variable nature of how BLM derived criteria compare to hardness based criteria. 82 of the 188 sites (44%) had BLM-derived criteria that were less stringent than those derived from the hardness based criteria equation (below and right of line in Figure 7).

Even at a single location, the relative stringency of the BLM and Hardness based criteria will change over time, with one resulting in more stringent criteria at some times of the year while the other does for different times of the year (Figure 8).

**Figure 8. BLM derived and hardness based criteria calculated from a single location on the Boise River from June 2014 to June 2015. For parts of the year the BLM derived criterion is more stringent, while for other times of the year the hardness based criterion is more stringent. Data are from the City of Boise (unpublished data).**

This disparateness is related to the seasonality of the BLM inputs and their importance to the BLM criteria. As has been discussed previously, even though the concentration of cations is a factor in the calculation of BLM criteria, the BLM is most sensitive to DOC and pH. However, the lowest concentrations of DOC in a stream usually coincide with the highest concentrations of cations, meaning that when hardness dependent criteria predict that copper is least bioavailable, the BLM derived criteria will predict the greatest copper bioavailability and toxicity (Figure 9).

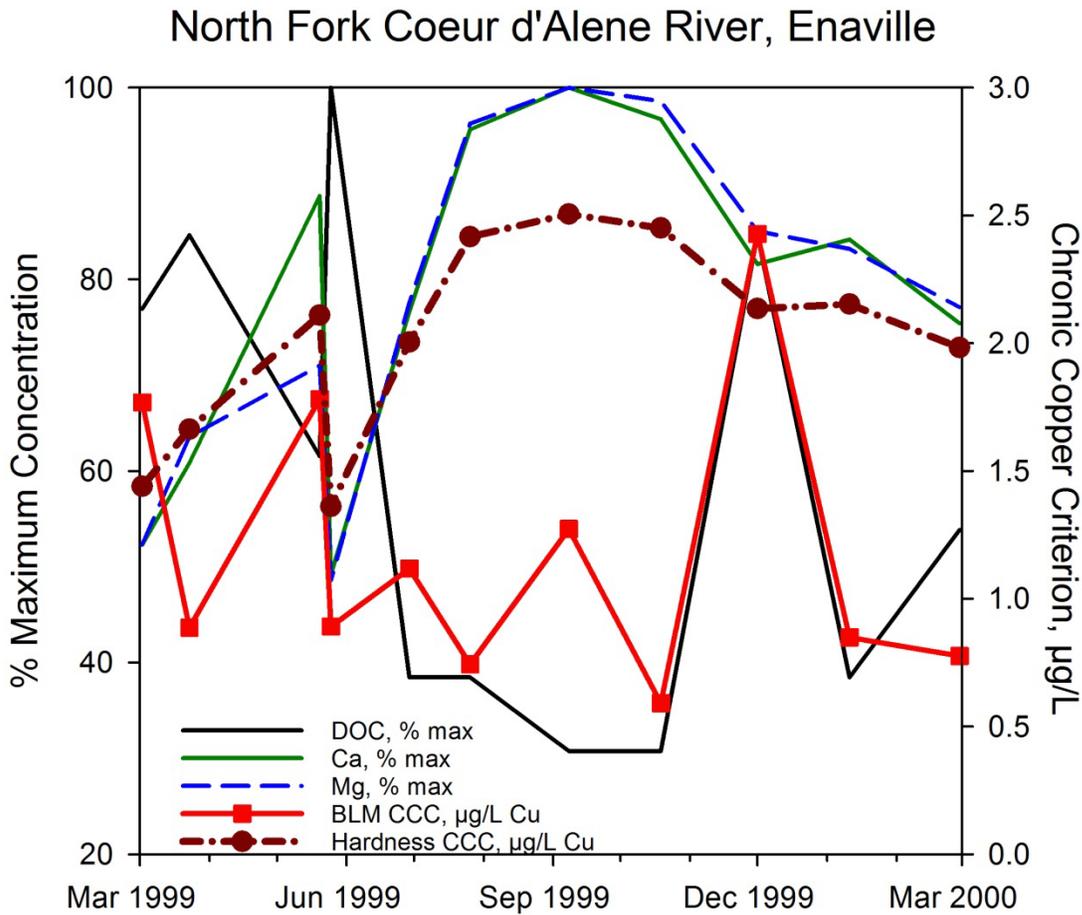

Figure 9. Temporal variability of major cation and DOC inputs to the BLM, BLM derived chronic copper criterion (CCC), and hardness based chronic copper criterion, from the North Fork Coeur d'Alene River, showing that DOC is at its lowest concentration when major cations (and hardness) are at their maximum, and that BLM derived copper criterion closely follows DOC, while hardness based copper criterion closely follows major cations.

## 5 Data Requirements for Application of the BLM

As described in Section 4.1, the BLM requires users to enter site chemistry in order to generate acute and chronic IWQCs. The following sections will describe the minimum data requirements for generating IWQCs using the biotic ligand model, each parameter and how it is measured, and the BLM's relative sensitivity to the different input parameters.

### 5.1 General Data Requirements of the BLM

The following section describes the required input parameters and the required measurement units for each parameter.

Temperature is an important physical characteristic of surface water and affects rates of chemical reactions. Temperature should be measured *in situ* at the time of sample collection. The BLM allows for temperature to be expressed in the following units: °C, °F, or K.

Chemical speciation is controlled in part by ambient pH. Therefore, the BLM for copper is highly sensitive to changes in pH. Like temperature, pH can be highly variable, and should be measured *in situ* in the field at the time of sample collection.

Dissolved organic carbon mitigates the effects of copper by complexing with free copper. It affects copper speciation and bioavailability. The BLM for copper is highly sensitive to changes in DOC. DOC is entered as a concentration; the BLM allows users to enter DOC concentrations in the following units: mg C/L, mmol C/L.

The major cations ( $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Na}^+$ , and  $\text{K}^+$ ) compete with copper at the biotic ligand site and affect copper toxicity. Of the major cations used in the BLM,  $\text{Ca}^{2+}$  and  $\text{Na}^+$  are the most important for copper toxicity. The major cations are entered as a concentration of the dissolved metal and can be entered in the following units:  $\mu\text{g/L}$ ,  $\text{mg/L}$ ,  $\text{g/L}$ ,  $\mu\text{mol/L}$ ,  $\text{mmol/L}$ , and  $\text{mol/L}$ .

Major anions ( $\text{SO}_4^-$  and  $\text{Cl}^-$ ) affect ionic strength and charge balance. Concentrations of these ions can be entered in the following units:  $\mu\text{g/L}$ ,  $\text{mg/L}$ ,  $\text{g/L}$ ,  $\mu\text{mol/L}$ ,  $\text{mmol/L}$ , and  $\text{mol/L}$ .

Alkalinity is a measure of the buffering capacity of a sample. In natural surface waters, carbonate and bicarbonate ions are usually the largest contributor to alkalinity. These ions form complexes with free copper, reducing copper bioavailability. Alkalinity should be entered as  $\text{mg/L CaCO}_3$ .

Sulfide can affect copper bioavailability by affecting speciation. However, sulfide is very uncommon in natural waters, and therefore users should use a default value of near zero (e.g.,  $1.0 \times 10^{-8}$ ).

Humic acid fraction (HA) can be measured directly, but is not critical to the BLM calculation. In the absence of specific HA data users should enter a default of 10% for humic acid fraction of DOC.

Work by EPA (2012a) and the Oregon Department of Environmental Quality (ODEQ 2016) indicate that the BLM is most sensitive to changes in DOC and pH.

When using the BLM to implement the Idaho copper criteria for aquatic life, a “sample” refers to a complete set of the BLM input parameters as described in Table 1, collected at a single place and time.

Section 6 will detail options for estimating criteria when a sample is incomplete, i.e., when not all required parameters have been measured.

**Table 1. BLM parameters required to constitute a complete sample. Included are recommended analytical methods, preservative, holding times, and detection limits.**

Parameter	Analytical Method	Preservative	Holding Time	Detection Limit
Temperature and pH	Measured <i>in situ</i> , using properly calibrated equipment	N/A	N/A	N/A
Dissolved Ca, Mg, Na, K	EPA 200.7	4 °C. Filter with 0.45 µm filter as soon as practical. Acidify to pH <2 after filtration.	28 days unpreserved. 6 months preserved.	0.1 mg/L
SO <sub>4</sub> , Cl	EPA 300.0	4 °C.	28 days.	0.1 mg/L
Alkalinity	SM 2320 B	4 °C.	14 days.	10 mg/L
DOC <sup>a</sup>	SM 5310 B	4 °C. Filter with 0.45 µm filter within 48 hrs. Acidify to pH <2 after filtration.	7 days	0.1 mg/L

<sup>a</sup>Dissolved organic carbon (DOC) samples are especially susceptible to contamination from sample bottles and sample filtration. Special consideration should be given to ensure that DOC samples are not affected by filtering adequate volume of sample or flushing with deionized water prior to subsampling for DOC.

## 5.2 Special Considerations for Monitoring pH and DOC

It is well known that pH and temperature vary cyclically throughout a single day, and these cycles can be dramatic. The BLM is highly sensitive to pH, and daily pH cycles could result in dramatic changes in the BLM derived criteria. Therefore, when designing monitoring programs or assessing data for derivation of BLM criteria, users should consider using continuous pH data to capture the daily variability of pH at a given site, or collecting samples early in the day when temperatures and pH are generally at their lowest.

Dissolved organic carbon (DOC) samples are especially susceptible to contamination from sample bottles and sample filtration. To ensure that DOC samples are not affected, special consideration should be given to ensure that DOC samples are not affected by it may be necessary to filtering adequate volume of sample or flushing filters with deionized water prior to subsampling for DOC. Monitoring results from DEQ (2017b) suggest that many of the problems associated with meeting precision requirements from field replicates can be allayed by filtering samples in an analytical laboratory as opposed to in the field, as is required by 40 CFR 136 for National Pollutant Discharge Elimination System (NPDES) compliance monitoring.

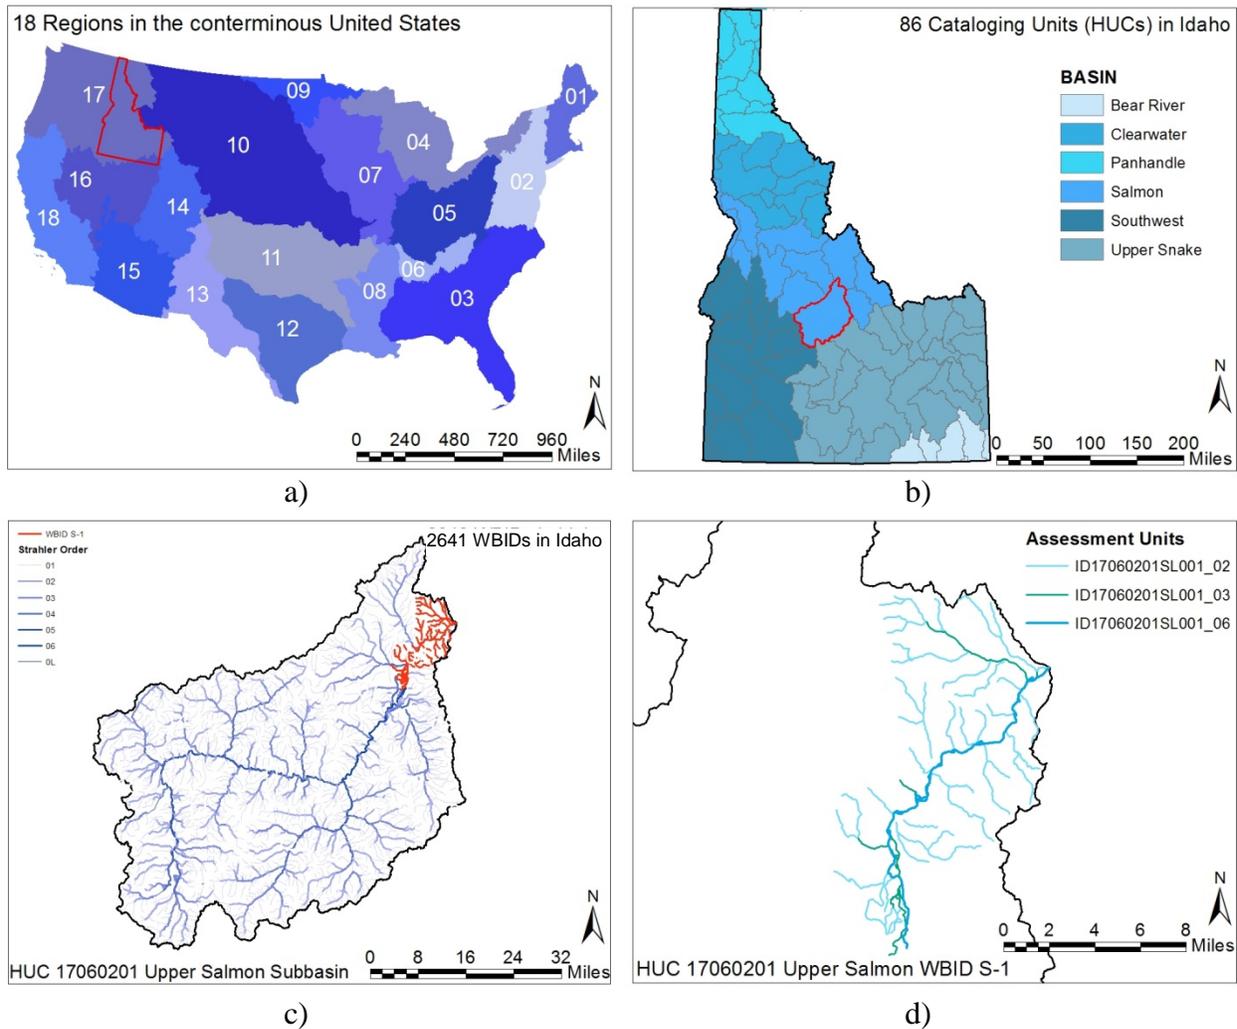

Quality Assurance Project Plans and monitoring plans for collection of BLM input parameters should clearly demonstrate how concerns for pH cycling and DOC data quality will be addressed and describe how monitoring will target the most bioavailable conditions for copper.

### **5.25.3 Spatial representation**

Physical and chemical parameters can be highly spatially variable. However, when implementing any criteria that are based on site-specific conditions, it is necessary that any single sample location be considered representative of a larger stream segment. How DEQ interprets spatial representation when implementing the copper criteria for aquatic life will depend upon how the data are to be used; whether monitoring results are intended to be used to determine compliance with water quality standards for the Integrated Report (IR) and TMDL development, or for development of effluent limits and determining compliance with NPDES permits. In flowing waters spatial representation is generally assured by sampling well mixed portions of the flow, i.e. sampling from the thalweg and avoiding confluences or other obvious lateral inputs.

#### **5.2.15.3.1 Ambient Monitoring for the Integrated Report and TMDL development**

When monitoring and assessing waters for the Integrated Report or for TMDL development, DEQ applies monitoring results and listing decisions from a single location or relatively short reach to a collection of waters with similar land uses known as an assessment unit, or AU. All waters within an AU can be reasonably expected to have the same ambient water quality and background water chemistry. AUs are numbered systematically, and are based on stratification of water body units identified in Idaho's water quality standards (IDAPA 58.01.02.109) by land use and stream order (Figure 10).

**Figure 10. Relationship between hydrologic unit codes (HUCs), water body units, and assessment units (AUs): (a) Level 1 regions in the nation; (b) 86 level 4 HUCs in Idaho (the highlighted HUC is 17060201—Upper Salmon River subbasin in central Idaho); (c) HUC 17060201, Upper Salmon River subbasin, with water body unit S-1 highlighted in red; and (d) water body unit S-1 subdivided into three different AUs (from DEQ 2016).**

AUs can be added or deleted as new information becomes available suggesting that a single AU should be split into multiple AUs due to changes in land use or other factors such as mapping errors; or that separate AUs should be grouped into a single AU.

Currently, there are 5,754 AUs in Idaho representing 95,119 miles of rivers and streams (DEQ 2014). More detailed discussions of AUs can be found in the most recent version of the *Integrated Report* (DEQ 2014) as well as the *Water Body Assessment Guidance* (DEQ 2016).

When conducting ambient copper and BLM monitoring for the IR or TMDL development, field crews must collect samples at locations that are considered representative of the entire AU being assessed. If multiple locations within an AU have been monitored, assessors should consider if locations are representative before combining data. If data are not considered representative, DEQ will provide sufficient rationale to describe why the sampling location is not representative

and that the data do not apply to the assessment unit. If some or all of the sampling sites are not representative of the water, then DEQ may opt to use none of the data or only use data from those sampling sites that do represent the AU.

### **5.2.25.3.2 Monitoring to Identify Criteria for Use in Effluent Limit Development**

It is necessary to characterize site-specific conditions within the receiving water when developing copper criteria for effluent limit development. Monitoring to determine effluent limits should occur downstream of points of discharge and below any regulatory mixing zones, where fully mixed conditions are expected to occur. Monitoring locations should represent the conditions for the receiving water as affected by the specific discharge being considered. If there are multiple points of discharge within a relatively short distance then a single site below all points of discharge may be necessary for characterizing conditions.

In some instances, it may be necessary or advisable to collect samples upstream of points of discharge in order to capture baseline conditions.

Monitoring results collected to identify criteria for use in effluent limit development may be used for IR assessment and TMDL development purposes, provided they are determined to be representative of the AU to which they belong.

### **5.35.4 Temporal representation**

In addition to determining the spatial extent that a sample represents, it is important to properly capture the temporal variability of the physical and chemical parameters that are used as inputs for the BLM. As described in Section 5.1, many of the input parameters can be highly variable, both short term (such as temperature and pH) and seasonally (such as DOC and major cations) (see Figure 9). This leads to highly variable IWQCs derived from a site (see Figure 8).

#### **5.3.15.4.1 Temporal Variability of BLM Parameters**

Temperature and pH can have seasonal as well as diel variability. In particular, diel pH variability has been shown to affect concentrations of metals (Brick and Moore 1996). It is important that monitoring programs consider the timing of sampling events in order to address this variability, particularly when evaluating acute effects (see Section 5.2).

~~It is well known that pH and temperature vary cyclically throughout a single day, and these cycles can be dramatic. The BLM is highly sensitive to pH, and daily pH cycles could result in dramatic changes in the BLM derived criteria. Therefore, when designing monitoring programs or assessing data for derivation of BLM criteria, users should consider using continuous pH data to capture the daily variability of pH at a given site, or collecting samples early in the day when temperatures and pH are generally at their lowest.~~

In addition, nearly all of the BLM input parameters exhibit some degree of seasonal variability. The degree of variability, and the relative predictability of seasonal variability, can be site specific.

Generally, 24 consecutive, monthly IWQCs calculated over the course of two years would be considered appropriate to characterize seasonal variability for any single site/location. However, users should consider any site specific factors, such as flood or drought conditions, that may require additional sampling in order to fully capture the variability at a site.

Comparison of flow data from the time of sample collection to the historical flow record may be used to demonstrate that sampling efforts appropriately captured the temporal variability and range of expected long-term flow conditions and that sampling frequency less than 24 months is appropriate.

Similarly, in some water bodies it may be advisable to calculate more than 24 monthly IWQCs in order to appropriately characterize seasonal variability at a site. In these instances, or whenever data are available, users may prefer to use longer term datasets to fully capture temporal variability at any given site.

Monthly sampling may not be possible at some sites in Idaho due to accessibility and safety considerations. For locations where monthly sampling is not practical, effort should be made to minimize the time period when there are no samples collected.

#### **5.3.25.4.2 Critical Time Period**

In many instances, the critical period of the year when copper is expected to have its greatest bioavailability, can be predicted and tied to seasonal variations of DOC. In Idaho, DOC is usually at its lowest concentrations in late fall through winter (see appendix C, NMFS 2014). This is consistent with other observed trends, where BLM-derived IWQCs were usually at their most stringent in fall and winter (EPA 2007b).

#### **5.45.5 Reconciling multiple IWQCs**

When evaluating time-specific results, users can compare a copper concentration to the BLM-derived IWQC calculated from the same sample.

However, in some instances, because IWQCs can be highly variable over time, it may be necessary for users to reconcile many different IWQCs in order to apply a single, consistent criterion, such as when determining the need for water quality based effluent limits.

The following sections describe possible approaches that may be used to reconcile multiple IWQCs from a single site when it is impractical to use individual IWQCs.

##### **5.4.15.5.1 Minimum of IWQCs**

The simplest approach to reconciling multiple IWQCs from a single site is to take the minimum of the IWQCs developed from the site. When using the minimum of IWQCs users would need to demonstrate that critical conditions have been captured. This demonstration may rely on information from nearby sites, historical flow records, or other data sources.

This approach is the most conservative. However, this approach is most appropriate -when there are relatively few data and therefore lower confidence that the temporal variability at a site has been sufficiently characterized.

### **5.4.25.5.2 Distribution of IWQCs**

One common approach to reconciling time variable criteria is to select a relatively conservative value from the distribution of criteria. When sufficient data are available to fully characterize the seasonal variability of IWQCs, ~~then a~~ then a conservative percentile of all IWQCs should be used. Users must demonstrate that the selected percentile will be protective of aquatic life and will not lead to a frequency of copper exceedance of individual IWQCs at the site more than once in three years.

### **5.4.35.5.3 Statistical approaches**

Other, more sophisticated statistical approaches can be used to reconcile multiple IWQCs from a single location. For example, the Fixed Monitoring Benchmark (FMB) may be used to evaluate compliance with time-variable criteria. The FMB uses the relationship of copper and individual IWQCs and their variability at a given site to derive a benchmark concentration that would comply with the frequency of exceedance component water quality criteria. For more information on the FMB, see EPA (2012a). Users may choose to use statistical approaches, such as the FMB, when sufficient data are available to fully characterize the variability of IWQCs and the relationship of IWQCs to copper concentrations. In some cases, it may require up to three or more years of monthly samples for all BLM input parameters as well as copper to fully characterize the variability of flows and water quality within a waterbody.

### **5.4.45.5.4 Seasonal Criteria**

For waters with predictable seasonal variability of IWQCs, seasonal criteria may be developed. For example, in waters with sufficient IWQC data, it may be possible to derive dry season criteria based on the distribution of IWQCs during low flow conditions, and wet season criteria based on the distribution of IWQCs during high flow. In order to consider seasonal criteria, sufficient data must be available and must demonstrate predictable seasonality. This would generally require at least 24 monthly samples, and may require multiple years of monthly samples to fully capture the variability and flood cycle.

## **6 Estimating Criteria when data are absent**

In order to derive criteria the BLM requires complete samples. However, at times, data may be limited, with either incomplete samples with certain parameters missing, or no samples available for a specific waterbody. In these cases, users may choose to estimate criteria based on available data.

~~This section will detail approaches for estimating criteria when data are absent or incomplete.~~

### **6.1 Estimating Input Parameters**

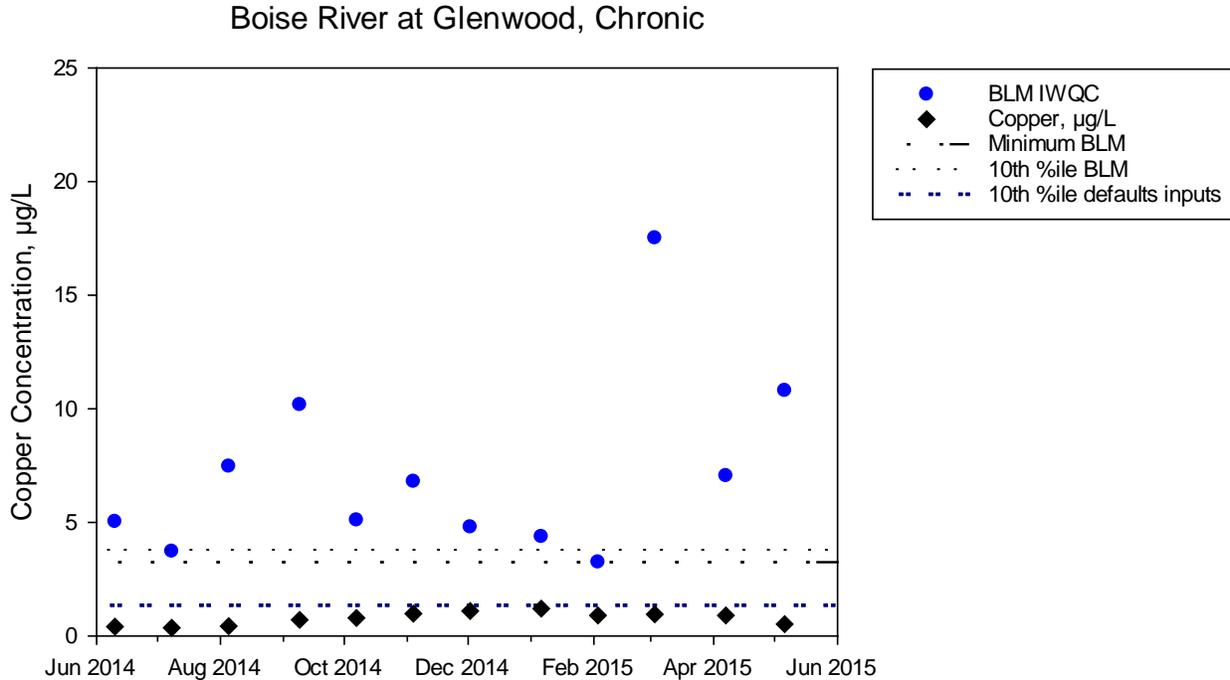

~~Users seeking to estimate copper criteria when data are absent may use statistical methods to estimate major geochemical ions, but should not use estimates of either DOC or pH.~~

~~Many of the BLM input parameters are predictable and can be estimated using statistical approaches (e.g., ODEQ 2016, EPA 2016). For example, concentration of major cations can be inferred based on ecoregions (EPA 2013) or specific conductance (ODEQ 2016).~~

~~Analysis of state wide data in Oregon showed that estimating geochemical ion concentrations (Calcium, Magnesium, Sodium, Potassium, Sulfate, Chloride, and Alkalinity) based on specific conductance did not significantly affect BLM outputs when compared to measured concentrations (ODEQ 2016).~~

While it may be possible to estimate conservative concentrations of geochemical ions and DOC based on statistical approaches, (e.g., EPA 2016), this approach may be overly conservative. For example, a minimum BLM chronic criterion of 3.25 µg/L was calculated from monthly samples for the Boise River at Glenwood Bridge. According to Appendix B of the missing parameters document (EPA 2016), the 2.5th percentile of BLM IWQCs is sufficient for protection of aquatic life; the 2.5th percentile of BLM chronic IWQCs at the Boise River at Glenwood Bridge site was 3.38 µg/L. By contrast, using the recommended 10<sup>th</sup> percentile of GI and DOC inputs as recommended by EPA (2016), and a conservative pH of 7, would give result in a BLM chronic criterion of 1.35 µg/L. This is less than half of the minimum IWQCs calculated at that site (Figure 11).

In addition, using lower percentile values from each of the inputs to the BLM may ignore the lack of synchronicity in natural seasonal variability of these parameters; for example, DOC often is at its lowest concentration during low flow conditions. However, at this time, many of the geochemical ions are at their highest concentrations (Figure 9). Ignoring such realities and taking low end inputs across the board can result in unrealistic and needlessly stringent criteria.

**Figure 11. Biotic Ligand Model (BLM) calculated chronic criteria for the Boise River at Glenwood Bridge, June 2014 - 2015. Reference lines demonstrate the criterion that would be calculated from the 10th %ile and minimum of IWQCs calculated from these data, and the criterion calculated using the EPA (2016) recommended default inputs. Data from the City of Boise.**

A more realistic approach than using conservative default inputs values would be to instead calculate BLM derived IWQCs for geographical regions and then recommend default criteria. This would more accurately reflect water quality at a given site at a given time, and would be easier for states to implement.

It may be possible to estimate conservative criteria based on data collected during the critical time period when IWQCs are expected to be at their minimum.

### **6.26.1 Critical Conditions Estimating Conservative Criteria**

When no data are available, when DOC or pH data are absent, or when available data are determined to not adequately characterize critical conditions, ~~default conservative~~ criteria estimates may be used to estimate critical conditions of a water body or AU and to ensure estimated criteria are protective of aquatic life.

In the late summer and fall of 2016, DEQ collected full BLM input data from 188 sites throughout the state. BLM criteria were generated from each sample. Sites were grouped according to the following regional classification systems:

- Idaho administrative basins as described in Idaho Water Quality Standards; hereafter referred to as Basins (IDAPA 58.01.02.109-160)

- Level III Ecoregions; hereafter referred to as Ecoregions (EPA 2013)
- Stream Order
- Water Body Assessment Guidance Site Classes; hereafter referred to as Site Class (Jessup (2011; DEQ 2016b)
- Site Class combined with stream size, where rivers are any water with stream order  $\geq 5$ , while streams are any water with stream order  $< 5$ ; hereafter referred to as Site Class + River/Stream.

~~DEQ's stream biological site classification system (Figure 12). For more information on development of DEQ's stream biological site classes see Jessup (2011). The distributions of resulting BLM IWQCs for each site class are shown in Figure 13.~~

~~**Figure 12. DEQ biological site classes for streams (Jessup 2011).**~~

~~**Figure 13. Distribution of BLM-derived CCC (chronic) copper criteria from late summer-fall samples collected in 2016 (DEQ 2017b) for each biological stream site class.**~~

~~One possible approach for estimating critical conditions may be based on the 10<sup>th</sup> percentile of derived BLM IWQCs for DEQ Stream site classes (Figure 12; Jessup 2011). For example, when conducting reasonable potential analysis (RPA) in a waterbody in the Mountain site class where no BLM data are available, the permit writer may choose to use the 10<sup>th</sup> percentile of copper IWQCs from the Mountain site class to estimate the copper criteria (Table 2). If the resulting RPA does not indicate a reasonable potential to exceed, than no further analysis is required. If RPA does indicate a potential to exceed the estimated criteria, then the discharger may decide to conduct additional monitoring to fully characterize the waterbody, or may decide to accept water quality based effluent limits based on the estimated criteria.~~

**Table 2. Summary of results from the ~~Statewide Monitoring for Inputs to the Copper Biotic Ligand Model (BLM)~~ (DEQ 2017b), including number of sites monitored (N), minimum, and 10<sup>th</sup> percentile values of copper IWQCs for each of DEQs stream site classes.**

<b>Site Class</b>	<b>Mountains</b>	<b>Foot hills</b>	<b>PPBV</b>
N	59	31	98
Min Chronic IWQC (µg/L Cu)	0.73	2.6	0.35
10 <sup>th</sup> %ile Chronic IWQC (µg/L Cu)	1.52	3.96	3.04

Conservative criteria can be estimated for a site by applying the lowest of the 10<sup>th</sup> percentile criteria calculated from the five regional classifications (DEQ 2017b). Table 2 presents potential conservative criteria estimates for each regional classification system.

**Table 2. Potential conservative criteria estimates. Values represent the 10th percentile of BLM criteria derived from statewide monitoring (DEQ 2017b).**

<b>Estimated copper criteria</b>		
<b>Regional Classification</b>	<b>10th percentile (µg/L)</b>	
	<b>Acute</b>	<b>Chronic</b>
<b>Basins</b>		
<u>Bear River</u>	<u>7.9</u>	<u>4.9</u>
<u>Clearwater</u>	<u>7.6</u>	<u>4.7</u>
<u>Panhandle</u>	<u>1.1</u>	<u>0.7</u>
<u>Salmon</u>	<u>3.9</u>	<u>2.4</u>
<u>Southwest</u>	<u>9.3</u>	<u>5.8</u>
<u>Upper Snake</u>	<u>2.6</u>	<u>1.6</u>
<b>Ecoregion</b>		
<u>Blue Mountains</u>	<u>10.1</u>	<u>6.3</u>
<u>Central Basin and Range</u>	<u>14.3</u>	<u>8.9</u>
<u>Columbia Plateau</u>	<u>7.2</u>	<u>4.5</u>
<u>Idaho Batholith</u>	<u>3.9</u>	<u>2.4</u>
<u>Middle Rockies</u>	<u>8.4</u>	<u>5.2</u>
<u>Northern Basin and Range</u>	<u>13.0</u>	<u>8.1</u>
<u>Northern Rockies</u>	<u>1.4</u>	<u>0.9</u>
<u>Snake River Plain</u>	<u>3.2</u>	<u>2.0</u>
<u>Wasatch and Uinta Mountains</u>	<u>9.0</u>	<u>5.6</u>
<u>Wyoming Basin</u>	<u>38.6</u>	<u>24.0</u>
<b>Stream Order</b>		
<u>1</u>	<u>5.2</u>	<u>3.2</u>
<u>2</u>	<u>3.7</u>	<u>2.3</u>
<u>3</u>	<u>4.0</u>	<u>2.5</u>
<u>4</u>	<u>1.6</u>	<u>1.0</u>
<u>5</u>	<u>8.9</u>	<u>5.5</u>
<u>6</u>	<u>2.3</u>	<u>1.4</u>
<u>7</u>	<u>10.1</u>	<u>6.3</u>
<u>8</u>	<u>7.6</u>	<u>4.7</u>
<u>Unassigned</u>	<u>9.0</u>	<u>5.6</u>
<b>Site Class</b>		
<u>Mountains</u>	<u>1.4</u>	<u>0.9</u>
<u>Foothills</u>	<u>6.3</u>	<u>3.9</u>
<u>PPBV</u>	<u>5.3</u>	<u>3.3</u>
<b>Site Class + River/Stream</b>		
<u>Foothills River</u>	<u>9.7</u>	<u>6.0</u>
<u>Foothills Stream</u>	<u>4.7</u>	<u>2.9</u>
<u>Mountains River</u>	<u>3.9</u>	<u>2.4</u>
<u>Mountains Stream</u>	<u>1.0</u>	<u>0.6</u>
<u>PPBV River</u>	<u>5.0</u>	<u>3.1</u>
<u>PPBV Stream</u>	<u>5.5</u>	<u>3.4</u>

For example, following scenario illustrates how conservative and protective criteria could be estimated for a new discharge permit. Aa new permit is proposed in an AU where there are no BLM input data available to determine site-specific copper criteria. The permit writer determines

that the site is in the Salmon basin, in the Middle Rockies ecoregion, is a 3<sup>rd</sup> order stream, and is in the Foothills site class. Using this information, the permit writer determines that conservative acute and chronic copper criteria estimates would be 3.9 and 2.4 µg/L, respectively (Table 3).

**Table 3. An example of conservative criteria estimates based regional classification systems. Values in bold indicate the minimum of these values, and would serve as the estimated criteria in this example.**

<b>Regional Classification</b>	<b>Estimated Conservative Criteria</b>	
	<b>Acute (µg/L)</b>	<b>Chronic (µg/L)</b>
<u>Salmon Basin</u>	<b>3.9</b>	<b>2.4</b>
<u>Middle Rockies</u>	8.4	5.2
<u>3<sup>rd</sup> Order Stream</u>	4.0	2.5
<u>Foothills</u>	6.3	3.9
<u>Foothills Stream</u>	4.7	2.9

The permit writer can use these conservative criteria estimates to perform reasonable potential analysis (RPA) in order to determine if there is a reasonable potential to exceed (RPTE) copper criteria. If the resulting RPA does not indicate RPTE, then no further analysis is necessary. If the RPA indicates RPTE, then the permit writer would use the conservative estimate of criteria to develop water quality based effluent limits following procedures outlined in the *Effluent Limit Development Guidance* (DEQ 2017a). Additionally, the discharger should initiate monitoring of BLM input parameters in order to confirm or refine applicable criteria once sufficient (e.g., 24 monthly) data are collected.

Users may propose alternative methods for estimating protective criteria. The proposed estimates must be based on scientifically sound methods and must be demonstrated to be protective of aquatic life. Analysis similar to what is found in DEQ 2017b would be considered sufficient to demonstrate protectiveness.

## 7 Identifying Impairments for the Integrated Report

The process of assessing whether a waterbody fully supports designated and existing beneficial uses is governed by IDAPA 58.01.02.054. DEQ uses the *Water Body Assessment Guidance* (DEQ 2016) as a guide in making assessment decisions.

Under IDAPA 58.01.02.054.05, data used for developing copper criteria for IR assessment purposes should be representative of the AU being assessed (see Section 5.2.1).

It is recommended that copper assessments be based on paired dissolved copper and complete BLM parameter sample results. When copper data are associated with complete BLM parameter

results, assessments should be based on direct comparison to the IWQC associated with the dissolved copper sample.

When evaluating copper exceedances, assessors must ensure that the frequency of exceedance requirement is met before listing a waterbody as impaired. This requires at least two exceedances of an acute or chronic criterion within three years. Therefore, a single exceedance of an IWQC is not sufficient for listing. If assessors only have one paired copper and IWQC sample, they must make an effort to collect at least one additional sample to confirm the IWQC exceedance prior to listing the water as impaired.

DEQs approach to ambient water quality monitoring relies heavily on biological monitoring. This approach uses direct measures of the aquatic community (e.g., benthic macroinvertebrates, fish) to assess aquatic life use support. This approach ensures that waters where copper (or any other pollutant) are impairing aquatic life are properly identified as impaired regardless of availability of BLM input parameter data to know the IWQC.
